Creative Inertia

I'm a designer focused on creating designs and assets that feel intentional, purposeful, and provoking.

I started in graphic design, building a foundation in branding, typography, and composition at one of Idaho's first technical education schools; Meridian Technical Charter High School in the Design Program; Earning my Adobe Suite Certs and began work as a production artist after my time in the USCG. Over time, I realized that while I valued the structure of being a production artist, I wanted to push beyond it; into work that carries more personality, cultural influence and makes a difference to my clients. After a layoff at a design studio where I was a Project Manager I went back to University to enhance my skills as a Designer.

I completed my bachelor's degree in Visual Communication Design at Eastern Washington University. Alongside that, I started RevWorxZ Designs Studio as a space to explore identity driven work across both digital and physical mediums. Prior to EWU, I Graduated from the College of Western Idaho with my AAS in Liberal Arts.

I approach design as both structure and expression. Design isn't just about art, animation, visuals or communication to me; It is about the act of solving problems, or creating new experiences. Thus why I love to computer science and engineering as well. I care about the strong fundamental principles of Design, but I'm more interested in using my personal expression to create Brand Designs, Motion Graphics, 3D assets and more that actually resonates; work that doesn't just look good, but feels personal to my community.

RWZDesigns.com Rebrand & Web App.

RevWorxZ Designs is a design company that I started one year ago. The main focus was in regards to livery and brand design. However, due to a desire to switch paths towards a more personal meaningful direction of tattoing while studying abroad in Japan and wanting to maintain the original heritage a Brand Redesign was needed. The project itself called for a logo redesign, website redesign, and additional content creation and increasing traffic to the website. The content created in this project takes RWZ from being a livery and apparel design company only to being an design studio specializing in tattoo application & design and still offering my companies original services, while also helping build clientele in Japan.

Client: (Bea Smith) RevWorxZ Designs

Tasks: Logo Redesign, Website Redesign, Content Creation, Licensure

Design Tools: Astro, Tailwind CSS, JavaScript, Illustrator, ProCreate, Google Dev Tools

Key Metrics: Succesful Sales (\$2,000+), Web Traffic Increase

Dates & Timeframes: April 21, 2026 - May 31, 2026

Link to Final Project: <https://RWZDesigns.com/>

RWZ Research

The project began with the desire to maintain RWZ's heritage while updating it to suite becoming an Japanese Traditional Tattoo Design and Livery Studio. First taking the old logo and then drawing concepts, which first started as the backbone of the rest of the rebrand after researching similar brands. While also notating what needs to change on the current site. I knew that since my audience would be in America and Japan it needed to appeal to both. Thus a creative brief was created to establish the purpose and audience of the work.

Week 1 - Brand Audit + Research Foundations

Focus: Direction and understanding the current landscape
Audit RWZ (website, visuals, messaging)
Define updated positioning (tattoo and apparel focus)
Identify target audience
Research 3-5 tattoo artists and apparel brands
Analyze content style, posting patterns, and client engagement methods

Output:
Brand positioning statement
Audience profile
Research notes (patterns and insights)

Initial notes -the biggest thing I have noticed in the popular profiles I have shown below is consistency and mastery in a specific direction including in their advertising. Its built on their experience, history and more.

When analyzing my website and brand it is difficult to tell what exactly it is that I do. As with the other pages I follow it is easy to tell what services they offer. Except for hitsuji goods. She is a more main stream designer, developer similar to my current skillsets. But the kind of content she posts is similar rather than all over the place.

Tattoo Websites: 25+ Well-Designed Examples (2026)

A collection of well-designed tattoo artist/studio websites made with top website builders like Squarespace, Wix, WordPress, Webflow, etc.

My Answer.

1. I found clients and people buying my street wear. 2. I have inspired tattoos with traditional Japanese tattoo inspiration. (This will translate to my clothing brand choices as well). People love my illustration work, tattoo line work and car area design to the combination. 3. I've been posting on Instagram mainly. Reels and story and posts. 4. I have other people in business my work when compliment. 5. I feel like I need more work before reaching out to show my skills. Which might help friends being like. However, the last one I did and have to think to really looking. And what to say in DMs. I have one person who viewed my story who messaged me but I need to connect them. I can always provide screenshots. 6. I don't feel ready this week specifically to send. Tomorrow I will send more variety of work to show. If anything, the outreach I'll want to be get clients to practice with and build my portfolio. 6. RWZ is my studio and practice. But I want to be personal.

1.) First goal: Get real skin + real people to build portfolio (Not high paying clients). - Yei.

2.) Second goal: Streetwear Sales
Not selling yet. (building interest)
- Audience
- validation
- taste alignment.

Initial Creative Brief and Illustrations

Old Website Layout

-replace tagline
-replace logo

-replace Statement here.

-more personal.

-contact page

-Display completed works in Flash

-update process page.

Original Branding & Site Layout

ベア スミス

Content Design

In addition to the redesign, part of the project included creating content for the site, social medias and more. The below two pieces are part of this process. The image on the right is an background animation for the site that can be seen via the QR Code on the right of the slide. The Logos on the top right are inspired from the original RWZ logo, while integrating the Kanji for RevWorxZ supported by the backbone/heritage of the original.

Final Product

Each page of the site was redeveloped with both American and Japanese Audiences in mind. The layout of the site was not changed via desktop. However, it was modified to fit phones & tablets more appropriately. The content was changed and input for translation, additional portfolio development, licensures, and to still allow for further development of the livery creation and traffic to the site was increased leading to further client contact.

Updated RWZ Web App. Including All New Assets. Also Mobile Displays

VRChat World & Game Development

For this project I was tasked with developing the brand, world, assets, and game logic for a server called the Rose Garden Casino within the game VRChat. For the project, I developed the server's logo, and banner for the server's homepage. I also created a new world for the server based off schematic drawings created. The assets created for the world included the 3 story casino with lobby, bar, sunroom, fountains, theatre, blackjack, poker, roulette tables and surrounding scenery. These assets were taken from blender and input into Unity; then using the VRChat SDK and Udon Game logic, physics, texture and other functionality were added to the assets to create a new world for the server and other users.

Client: Rose Garden Casino Server

Tasks: 3D Modeling / Unity Development / VRChat SDK / Brand Dev.

Platforms: PC, VRChat

Design Tools: Illustrator, Blender, Unity, ProCreate

Key Metrics: Player Base, Functionality, Client Contentment.

Dates & Timeframes: December 2025, April 2026

Brand Development

For this project, I was helping the Rose Garden Server create a distinguished brand that way they could be noticed within the VRChat community. The server already had some ideas of what they wanted which is shown via the sketch on the right. From this, I used Adobe Illustrator and concepting in order to produce the brand's logo, and banner. The logo would also be used in other areas of the project which will be shown within the next few pages.

Rose Garden Casino (Sketch to Asset Creation)

Asset Creation

With a basic sketch shown above (left), and some brainstorming the Rose Garden Casino server wanted a world that did not exist in VRChat yet. Instead of a poker room, or a blackjack room or bar world which is typical for the game; they wanted a world where all existed simultaneously. Thus, I got to work creating the basic assets needed to accomplish this mission within blender. First the fascia was created and the remaining assets were each hand crafted and optimized to allow for all the desired needs. These assets are then imported into Unity to be textured, add physics and game mechanics, and lighting.

ベア スミス

Unity & Publishing

After all the assets were completed and optimized in blender, I saved each one as an FBX file and imported them into Unity. In Unity I was able to go through each asset thanks to my file naming conventions and texture the models, add system efficient baked lighting, and game functionality to each of the tables from roulette, poker and black jack along with the TV's which connect to external websites. I was also able to add physics to the building and other objects which creates an welcoming atmosphere for the player. Once all the parts of the world and games worked within player testing using the VRChat SDK in Unity I published the world to allow the Rose Garden Casino Club to use this as their home world. The world can be found below. Currently the world is only available to PC users. With further optimization it will become multiplatform.

Neural Network Development

NVIDIA NeuralAngelo

System Development / Algorithm Modification / Programming

For this project I wanted to refine a 3D modeling AI model called NeRf created by NVIDIA in order to be able to use assets I found in real life in videogames or for 3D Printing. Over the course of 10 weeks, I refined the creation of other prior researchers from John Hopkins called NeuralAngelo. I refined the algorithm used in the system, and created an easy install process for others to use due to the system dependency issues that made the program unuseable for many.

Platforms: Windows, Linux, Android

Design Tools: Python, G++, C++, Typescript, Unity, Unreal, NeRF and NeuralAngelo

Key Metrics: Improved Algorithm, Assets Created and Used within Unreal and 3D Printed

Dates & Timeframes: January 2025, April 2025

ベア スミス

Initial Research

For this project, I wanted to see if I could attempt to replace LIDAR 3D scanning with an AI model. I set up a newly obtained machine for Instant-NGP, (which is a program I had used for a research project prior which I believed at the time created 3D models from the ColMap process.) fixed missing C++/VCRUNTIME issues, updated graphics drivers, and confirmed the new 2070-based setup produced stronger results than my previous GTX/i5 machine. I then tested multiple vehicle datasets, including Mercedes and Ferrari footage, adjusting parameters like AABB scale, bounding boxes, PNG density, and Laplacian smoothness to improve mesh quality. These tests showed that reflective vehicle surfaces, motion blur, poor camera angles, and repeated COLMAP camera positions can create holes, duplicated geometry, and weak model outputs, but manually correcting bad camera data improved the results. I also tested exporting the generated 3D renders into Unreal Engine and found that the workflow is theoretically possible, but NGP's mesh extraction was not stable enough for clean game-ready models. Finally, I experimented with creating a Sora-based video generation agent for producing 360-degree car datasets, but the results showed that current AI video tools still struggle with object permanence and consistent rotational views, leading me to focus on creating my own footage for better datasets moving forward.

NeuralAngelo

Knowing even with better datasets that NeRF would not produce 3D models formatted in a surface mesh which is what is best optimized for gameplay and 3D Prints. I began to research similar models to see if one existed. As NeRF used radiance field values based upon frames of a video collecting RGB values through a process called colmapping I started searching using colmapping. I found an model called NeuralAngelo developed by John Hopkins University 2 years prior. The model was orientated to produce surface meshes of large areas, and wasn't developed for exporting its meshes well. However, it used colmapping as it's dataset. Therefore I had a place to start that I understood. Over the course of 4 weeks, I produced an subsystem to run the model on which included correct dependencies, and refined the algorithm to allow Neuralangelo to process smaller scenes better with more details in an attempt to produce better results than my initial research.

First Print Attempt using the exported FBX from NeuralAngelo

Linux Subsystem Install

Integrated Algorithm Modification (Gains)

Export of same footage from other model.

ベア スミス

Refinement

Even with a successful install of NeuralAngelo, and algorithm modification the biggest issue the model had compared to lidar was occurring during the colmapping process. If the footage had large reflections the RGB values returned were offset, thus leaving holes in the model itself. In order to fix this the footage needed to be recorded in a controlled environment; thus I started creating a new dataset in a neutral environment (bottom left). This alongside working on changing NeuralAngelo's optimization algorithm with John Hopkins to use RGB synthesis loss to make the generated image match the original input, but it also adds Eikonal loss to keep the SDF surface normals stable and unit-length, and curvature loss to prevent the model's geometry from becoming overly distorted or noisy. Overall, this means the model is not just trying to make the render look correct visually; it is also regularizing the underlying 3D structure so the final surface is cleaner, smoother, and more usable for mesh extraction. After the algorithm modification and controlled footage the 3D model produced fully resembled the recorded footage. Making this research a success.

Model created from uncontrolled environment.

RGB Synthesis, Eikonal Loss and Curvature Loss optimization.
